- 64) Heat stable tetrafluoroethylene- perfluoro (alkyl vinyl ether) copolymers.
- (5) A tetrafluoroethylene-perfluoro(alkyl vinyl ether copolyme) in which heat unstable carbinol end-groups (-CH<sub>2</sub>OH groups) present have been protected against heat degradation by treating the copolymer with NH<sub>3</sub> or NH<sub>3</sub> producing compounds.

-COOH, groups with evolution of hydrogen fluoride (HF). HF is a reactive, corrosive acid and its presence causes difficulties in molded articles derived from TFE/FAVE copolymers that contain the original -CH<sub>2</sub>OH end groups. In addition, the -COOH groups degrade on fabrication of the polymer to produce gases (CO<sub>2</sub>) that produce undesirable bubbles in molded articles.

The raw polymer, as made, contains some -COF and -COOH end-groups and these decompose also, along with the -COF and -COOH groups formed from decomposition of the -CH<sub>2</sub>OH end-groups.

### SUMMARY OF THE INVENTION

In an effort to reduce the number of -COF and -COOH end-groups, it has now been discovered that 15 those groups present in the raw polymer, as made, can be converted to amide end-groups. It has also now been discovered that this conversion to amide groups of the original -COF and -COOH end-groups surprisingly imparts thermal stability to the 20 -CH2OH end-groups and retards their decomposition. Accordingly, this invention is directed to a means for stabilizing the carbinol (-CH2OH) end groups to retard their decomposition to -COF groups and, in 25 turn, the breakdown of the -COF groups to form corrosive HF and undesirable -COOH end groups. stabilizing means is not completely known or understood, but it has now been found that when TFE/FAVE copolymers containing -CH2OH, -COF and -COOH end groups (which are conveniently made in the presence of halocarbon solvents and an alcohol) are treated with nitrogen-containing compounds such as ammonia or ammonia-producing compounds such as ammonium salts or organic amines, the resulting material has enhanced propensity against

To treat these copolymers with nitrogen compounds to convert the -COF and -COOH groups to amide groups, the copolymer is simply contacted with the nitrogen compound. Ammonia vapor is the 5 preferred nitrogen compound and it can be simply passed into a closed container containing the copolymer for a desired amount of time or can be passed over or through a bed of the copolymer for a desired amount of time. The copolymer can be agitated during contact if desired. The form of the 10 copolymer is not important; it can be in flake, cube, pellet or article form. The atmosphere in the container can be 100% NH2 or can be as little as 0.1% by volume NH3 (with the remainder being air or inert gases). In dilute form, 1-30% by volume is 15 preferred and 10-30% most preferred. Contact time is long enough to achieve the desired degree of conversion to amide end groups, usually at least 50%, and preferably about 100%. The time is usually between 1/2 to 24 hours, with 1 to 7 1/2 hours 20 preferred and 2 to 6 hours most preferred. Temperature and pressure are not critical. Pressure is usually atmospheric, for convenience. Temperature is usually room temperature, 20-30°C, but can be between 0 and 100°C. Usually when -COOH groups are to be converted to amide groups, higher temperatures. are used.

When ammonia-forming ammonium salts or organic amines are used, the copolymer is ordinarily melted in contact with the nitrogen compound. A convenient means is to extrude the molten copolymer and the nitrogen compound. Among the nitrogen compounds that can be employed in this manner are

copolymer in water and measuring the amount of fluoride ions extracted into the water. Typically, raw copolymer will liberate 20ppm or more F ions based on weight of copolymer, whereas the treated copolymer liberates less than 5ppm F, and preferably less than 1.

#### DESCRIPTION OF MATERIALS AND TEST MEASUREMENTS

#### A. Polymer End Groups

The type and quantity of certain end groups
in the polymer were determined by the infrared
spectrum obtained on compression molded films of
about 10 mils (0.25 mm) thickness. The end groups of
interest and absorbance frequencies are shown below:

	End Group	Absorbance
15	Acid Fluoride (-COF)	1883 cm <sup>-1</sup>
	Carboxylic Acid (m) (-CO <sub>2</sub> H)	1810 cm <sup>-1</sup>
٠	Methyl Ester (-CO <sub>2</sub> CH <sub>3</sub> )	1795 cm <sup>-1</sup>
20	Carboxamide (-CONH <sub>2</sub> )	1768 cm <sup>-1</sup>
	Carbinol (-CH <sub>2</sub> OH)	3648 cm <sup>-1</sup>

The quantitative measurement of the number of these groups was obtained by the measurement of the extinction coefficients of each of these groups from model compounds and transferring these coefficients to the measurements obtained on the polymer. The end groups are expressed as the number per one million carbon atoms in the polymer.

#### B. Melt Viscosity

25

30

35

The melt viscosity is measured according to ASTM D-1238-52T modified by using a cylinder, orifice and piston tip made of a corrosion-resistant alloy (Haynes Stellite 19), by charging a 5.0 g sample to the 9.53 mm inside diameter cylinder which is

with a gas inlet tube at the bottom and vapor outlet port on the top. The vapor space/cube volume ratio was 1.8. Anhydrous ammonia (approximately 1.5 lbs) was introduced into the vessel through the gas inlet 5 tube over a 15 minute period. The inlet and outlet tubes were then capped and the polymer cubes were allowed to stand in contact with the dilute ammonia atmosphere for a 24 hour period at 22-25°C. The vessel outlet port was then fitted to an exhaust system while nitrogen was blown through the inlet tube to displace the NH3 treatment vapor. As shown below, infrared analysis of the polymer end groups before and after ammonia vapor treatment show that the carbonyl fluoride groups were converted to amide groups.

		Number of End	Groups/10°C
	End Group Functionality	Before NH <sub>3</sub> Treatment	After NH <sub>3</sub> Treatment
20	-COF -CO <sub>2</sub> H -CO <sub>2</sub> CH <sub>3</sub> -CONH <sub>2</sub> -CH <sub>2</sub> OH	26 0 39 0 197	0 0 56 36 210

15

- 30

The polymer was tested for fluoride ion extractability both before and after  $\mathrm{NH}_3$ 25 treatment. Results were as follows:

# Extractable Fluoride Ion Content

Before NH3	After NH <sub>3</sub>			
Treatment	Treatment			

22.8 ppm

1.0 ppm

Stabilization of the carbinol end groups to heat aging was demonstrated as follows: Samples of the polymers described above, before and after 35
